The Hospital Emergency Department (HED) stands out as one of the settings where patients are at a higher risk of experiencing some type of adverse event. In our setting, the EVADUR study (an observational, prospective, multicenter study, conducted in 21 Spanish HEDs), showed that some incident or adverse event occurred in approximately 12% of 3,854 patients seen. Of these incidents, 70% could have been prevented. Within adverse events that caused harm to the patient, 24.1% were drug-related, and it is estimated that around 30% of patients admitted to hospital through the HED will present some medication error (ME). The processes of preparation of medication and its administration have been identified as critical patient care in cases of intoxication, training for residents and students, etc.

The benefits of the incorporation of the Clinical Pharmacist as a member of the multidisciplinary team in the HED include improvements both in health and economic outcomes. Through their direct involvement in the review of medications, the Pharmacist has demonstrated being an agent able to reduce the ME rate, by detecting and intercepting them before they reach the patient. Moreover, half of patients managed in these units will present some DRP, mainly caused by lack of prescription of a necessary medication, or the use of treatments not recommended in their new clinical situation. The presence of the Pharmacist will ensure the detection as well as an early solution of these DRPs, representing savings of up to 20%.

In our setting, there has been a gradual increase in the incorporation of the Clinical Pharmacist to HEDs. The creation of the REDFASTER team work in 2006 has contributed to the development and visibility of this professional profile: its objectives include an improvement in the quality of patient care through a rational use of medication in the Emergency Unit, and the encouragement of collaboration in care, education and research with other healthcare professionals. According to data by the Spanish Society of Hospital Pharmacy (SEFH), approximately a fifth of Pharmacy Units provide, to some extent, Pharmaceutical Care for HEDs.

The implementation and leadership of reconciliation programs is another field developed by Pharmacists. It has been estimated that practically all patients present discrepancies in their lists of regular medication. The Pharmacist has demonstrated the ability to obtain a correct and complete pharmacotherapeutic anamnesis, identifying a higher number of regularly used drugs per patient than the clinician, probably due to the likelihood to spend a longer time interviewing the patient or relative. Likewise, it is easy to identify some DRP, mainly caused by lack of prescription of a necessary medication, or the use of treatments not recommended in their new clinical situation. The presence of the Pharmacist will ensure the detection as well as an early solution of these DRPs, representing savings of up to 20%.

In our setting, the use of medication is placed among the first causes of iatrogenesis as, unfortunately, in recent years an evolution has been observed towards a Clinical Pharmacist profile, able to offer a wide portfolio of services. This includes: adapting treatments to the formulary of each center, identifying a higher number of regularly used drugs per patient than the clinician, probably due to the likelihood to spend a longer time interviewing the patient or relative. Likewise, it is easy to identify some DRP, mainly caused by lack of prescription of a necessary medication, or the use of treatments not recommended in their new clinical situation. The presence of the Pharmacist will ensure the detection as well as an early solution of these DRPs, representing savings of up to 20%.
to detect reconciliation errors in a high percentage of those patients treated at the HED, the main cause is the omission of a treatment necessary for the patient. There is a high acceptance of pharmaceutical interventions by the Emergency Specialist, and more than half of reconciliation errors detected are considered clinically relevant. In the elderly population, it has been demonstrated that medication reconciliation, conducted through the incorporation of a Pharmacy Specialist, can reduce DRS in elderly patients at high risk of experiencing them who are managed at a short-stay unit linked with a HED.

In recent years, the role of the Pharmacist in clinical activities has also increased its value. The interventions conducted are supported by a high level of evidence, according to the clinical practice guidelines available, and have even been associated with a theoretical reduction in morbimortality. There have also been initiatives focused on highly prevalent conditions, such as atrial fibrillation and diabetes. In the case of atrial fibrillation, a high percentage of patients can present a negative result associated with medication, detection by the Pharmacist could contribute to an increase in the quality of patient care. Regarding diabetic patient care, the Pharmacist intervention contributes to an increase in adherence to the recommendations by the Spanish Society of Emergency Medicine about the hypoglycemic treatment prescribed. Finally, we must also highlight the creation of a work network, such as the antidote network: through a computer application, different Pharmacy Units are connected in order to ensure an effective action in cases of intoxication.

Regardless of positive results, the reality is that there is still an insufficient presence of the Pharmacist in HEDs. A priori, the main barrier is the lack of economic resources in the centers; however, this is not the only barrier. The idiosyncrasy of HEDs requires wide time coverage and reorganization both of the Pharmacy Unit and the Emergency Unit, in order to fit this new figure. A point of consensus is the need for the physical presence of the Pharmacist at the HED, because it facilitates access and allows a prospective validation of treatments. Therefore, it is necessary to work on the prioritization criteria for patients in this setting, for example selecting patients of advanced age, with multiple comorbidities and polypharmacy. Another strategy to consider is the development of tools supporting clinical decision (such as assisted systems for electronic prescription); however, there is still limited evidence about their utility.

Summing up, in recent years there has been an evolution in the role of the Clinical Pharmacist in HEDs, until they have become one more member of the multidisciplinary team, favorably valued by the rest of professionals. Among a wide range of actions, it is worth highlighting their involvement in treatment review and optimization, as well as their role in the prevention of MEs. From the perspective of Emergency Specialists, the role of the Clinical Pharmacist in the Emergency Unit represents a major help, undoubtedly, because HEDs are an area at special risk of adverse events associated with pharmacological treatments; therefore, in this high-risk setting, the protection activity conducted by the Clinical Pharmacist can be cost-effective.
